Subject: LAN Switch Question

Summary: The packet in question is using layer 2 Dynamic Trunk Protocol for switches to negotiate a trunk link.

This packet is using a protocol known as Dynamic Trunk Protocol. It is a CISCO protocol that's used to start a trunk link between two switches. Because this is a layer 2 protocol, it does not have an IP address, which is specific to layer 3.

This protocol has two major parts. The first is the Ethernet header. This header sends to CISCO's mutlicast MAC address (01:00:0c:cc:cc:cc) and contains the source router (e0:2f:6d:3a:a5:1a). It also contains the length of the packet.

The next part is the Dynamic Trunk Protocol (DTP). It contains the version number and the management domain name (blank in this case). After that it has the Trunk Status. This tells the second switch what the current state is (Trunk and ON in this case). It also lists Trunk Type, which is set to 802.1Q for both Operating Type and Administrative Type.

One point to note about this packet is that the source and the destination mac addresses are the same. This seems to indicate that the switch is talking to itself on it's own port.

If there are any concerns, questions, or clarifications, please do not hesitate to reach out.

With Regards,
Team 02
